TABLE STYLES INFERENCE ENGINE

TECHNICAL FIELD

The invention generally relates to electronic documents, and more particularly relates to a table styles inference engine to determine the formatting attributes of an existing table so that the formatting attributes can be converted into a table style and applied to other tables.

BACKGROUND

Some word processing program modules, such as the "WORD 10" word processing program module marketed by Microsoft Corporation of Redmond, Washington, include the concept of a table style. A table style is a collection of formatting attributes that may be applied to a table. The formatting attributes may include borders, shading, indentation and alignment, among others. The user may select a table style from a list of standard table styles and apply the table style to a table.

Even though standard table styles are useful, they do not allow a user to create their own table style from manual formatting and apply that style to other tables. So, if a user wants a table formatted differently than a standard table style, the user must either create the custom table style (using a user interface) or create and format the table manually. Users do not mind manually formatting a table and they often do so. However, users become frustrated when they are unable to apply formatting from a table

they have already created to another table and must repeatedly format a table the same way. Thus, one drawback of existing word processing program modules is that a user is not able to manually create and format a table and then automatically apply the formatting attributes to another table.

SUMMARY OF THE INVENTION

The present invention meets the above-described needs by providing a table styles inference engine. In one embodiment, the table styles inference engine is able to determine the formatting attributes of a user-defined table and create a table style from the formatting attributes.

In one aspect, to create a table style, the table styles inference engine determines the optimal body pattern to describe a user-created table. In order to achieve compatibility with existing table styles, an optimal uniform body pattern, an optimal row banding pattern and an optimal column banding pattern are determined. The user-defined table is analyzed assuming different uniform body patterns. The optimal uniform body pattern is then determined by determining the uniform body pattern that most closely matches the user-defined table. The user-defined table is also analyzed assuming different row banding body patterns. The optimal row banding body pattern is then determined by determining the row banding body pattern that most closely matches the user-defined table. The user-defined table is also analyzed assuming different column banding body patterns. The optimal column banding body pattern is then determined by determining the column banding body pattern that most closely matches the user-defined table. From these optimal body patterns, the closest match to the user-defined table is determined to be the overall optimal body pattern. The overall optimal body pattern is then saved as a table style.

That the invention improves over the drawbacks of the prior art and accomplishes the advantages described above will become apparent from the following detailed description of the exemplary embodiments and the appended drawings and claims.

DETAILED DESCRIPTION OF EMBODIMENTS OF THE INVENTION

An embodiment of the present invention will be incorporated into the "WORD 11" word processing program module marketed by Microsoft Corporation of Redmond, Washington. Briefly described, in one embodiment, the invention is a table styles inference engine that is able to determine the formatting attributes of an existing table in an electronic document and create a table style based on the formatting. The table style may then be used to apply the formatting attributes to other tables.

In one embodiment, the present invention solves the drawbacks of the prior art by extracting the formatting attributes of a table and converting them into a table style. For example, suppose a user manually formats a table with the first row having a purple background, the first column (excluding the top corner cell) having a gray background and having internal black horizontal borders. The user then inserts new tables and wants to format them in the same way. The user certainly doesn't want to apply shading to the first row and first column of every new table. Using an embodiment of the present invention, the user is able to format any new tables just like the one previously created. The inference engine in accordance with an embodiment of the present invention can examine the table and create a table style whose description is as follows:

1. first row is purple;

2. first column is gray;

3. top, left corner has formatting match the first row; and

4. the table has internal black horizontal borders.

When the user wants another table to look like the table described above, the user simply needs to apply the style, instead of manually applying all the formatting to every portion of the table. The table style also has the benefit that the formatting is updated

4

automatically as new rows and columns are added.

In a preferred embodiment, the present invention is compatible with the conditional formatting of the existing table styles feature of the "WORD 10" word processing program module. As described below under the Table Styles section, formatting attributes for a table style are not defined on a per cell basis, but instead are defined based upon portions of the table. For example, the left column may have different formatting attributes than the rest of the table. Thus, to achieve compatibility with existing table styles, in a preferred embodiment the present invention determines an optimal uniform body pattern, an optimal row banding pattern and an optimal column banding pattern. From these optimal patterns, the closest match to the user-defined table is found. The closest matching optimal pattern is then used as a table style.

Exemplary Operating Environment

FIG. 1 and the following discussion are intended to provide a brief, general description of a suitable computing environment in which the invention may be implemented. While the invention will be described in the general context of an application program that runs on an operating system in conjunction with a personal computer, those skilled in the art will recognize that the invention also may be implemented in combination with other program modules. Generally, program modules include routines, programs, components, data structures, etc. that perform particular tasks or implement particular abstract data types. Moreover, those skilled in the art will appreciate that the invention may be practiced with other computer system configurations, including hand-held devices, multiprocessor systems, microprocessor-based or programmable consumer electronics, minicomputers, mainframe computers, and the like. The invention may also be practiced in distributed computing environments where tasks are performed by remote processing devices that are linked through a communications network. In a distributed computing environment, program modules may be located in both local and remote memory storage devices.

5

With reference to FIG. 1, an exemplary system for implementing the invention includes a conventional personal computer **20**, including a processing unit **21**, a system memory **22**, and a system bus **23** that couples the system memory to the processing unit **21**. The system memory **22** includes read only memory (ROM) **24** and random access memory (RAM) **25**. A basic input/output system **26** (BIOS), containing the basic routines that help to transfer information between elements within the personal computer **20**, such as during start-up, is stored in ROM **24**. The personal computer **20** further includes a hard disk drive **27**, a magnetic disk drive **28**, e.g., to read from or write to a removable disk **29**, and an optical disk drive **30**, e.g., for reading a CD-ROM disk **31** or to read from or write to other optical media. The hard disk drive **27**, magnetic disk drive **28**, and optical disk drive **30** are connected to the system bus **23** by a hard disk drive interface **32**, a magnetic disk drive interface **33**, and an optical drive interface **34**, respectively. The drives and their associated computer-readable media provide nonvolatile storage for the personal computer **20**. Although the description of computer-readable media above refers to a hard disk, a removable magnetic disk and a CD-ROM disk, it should be appreciated by those skilled in the art that other types of media which are readable by a computer, such as magnetic cassettes, flash memory cards, digital video disks, Bernoulli cartridges, and the like, may also be used in the exemplary operating environment.

A number of program modules may be stored in the drives and RAM **25**, including an operating system **35**, an application program module **36**, such as Microsoft's "WORD 11" word processing program module including a table styles inference engine, other program modules **37**, and program data **38**.

A user may enter commands and information into the personal computer **20** through a keyboard **40** and pointing device, such as a mouse **42**. Other input devices (not shown) may include a microphone, joystick, game pad, satellite dish, scanner, or the like. These and other input devices are often connected to the processing unit **21** through a serial port interface **46** that is coupled to the system bus, but may be connected

by other interfaces, such as a game port or a universal serial bus (USB). A monitor **47** or other type of display device is also connected to the system bus **23** via an interface, such as a video adapter **48**. In addition to the monitor, personal computers typically include other peripheral output devices (not shown), such as speakers or printers.

5   The personal computer **20** may operate in a networked environment using logical connections to one or more remote computers, such as a remote computer **49**. The remote computer **49** may be a server, a router, a peer device or other common network node, and typically includes many or all of the elements described relative to the personal computer **20**, although only a memory storage device **50** has been illustrated in

10   FIG. 1. The logical connections depicted in FIG. 1 include a local area network (LAN) **51** and a wide area network (WAN) **52**. Such networking environments are commonplace in offices, enterprise-wide computer networks, Intranets and the Internet.

When used in a LAN networking environment, the personal computer **20** is connected to the LAN **51** through a network interface **53**. When used in a WAN

15   networking environment, the personal computer **20** typically includes a modem **54** or other means for establishing communications over the WAN **52**, such as the Internet. The modem **54**, which may be internal or external, is connected to the system bus **23** via the serial port interface **46**. In a networked environment, program modules depicted relative to the personal computer **20**, or portions thereof, may be stored in the remote

20   memory storage device. It will be appreciated that the network connections shown are exemplary and other means of establishing a communications link between the computers may be used.

Before describing different embodiments of the present invention, a brief description of table styles and definitions of terms will be provided below.

25   **Table Styles**

The "WORD 10" word processor program module, marketed by Microsoft Corporation of Redmond, Washington includes a feature known as table styles. A table style is a collection of formatting attributes that can be applied to a table and includes the

7

ability to specify formatting attributes such as:

1.   Borders and Shading;

2.   Table Properties, such as indentation and alignment; and

3.   Font and Paragraph properties for text inside the table.

One interesting thing about table styles is their ability to apply formatting conditionally, depending on the portion of the table. For example, the header row may have different formatting than the rest of the table. Table 1 lists the types of special cells, rows and columns within a table style which formatting attributes can be applied to independently:

Table section	Description
Whole table	Obvious
Header row	Obvious
Last row	Obvious
Left column	Obvious
Right column	Obvious
Odd row stripes	Each stripe can be comprised of an unlimited number of rows, but the number of rows in an odd row stripe must be the same as the number of rows in an even stripe.
Even row stripes	Each stripe can be comprised of an unlimited number of rows, but the number of rows in an odd row stripe must be the same as the number of rows in an even stripe.
Odd column stripes	Each stripe can be comprised of an unlimited number of columns, but the number of columns in an odd stripe must be the same as the number of columns in an even stripe.
Even column stripes	Each stripe can be comprised of an unlimited number of columns, but the number of columns in an odd stripe must be the same as the number of columns in an even stripe.
Top left cell	Obvious
Top right cell	Obvious
Bottom left cell	Obvious
Bottom right cell	Obvious

Table 1

5

Definitions of Terms

Table Style Properties: the formatting attributes that comprise a table style. Table 2
below lists the formatting attributes in a preferred embodiment of the present invention

along with the portion of a table the formatting attributes may apply to (row, cell or text).

Borders	Row
Shading	Row
BottomPadding	Cell
FitText	Cell
LeftPadding	Cell
RightPadding	Cell
TopPadding	Cell
VerticalAlignment	Cell
WordWrap	Cell
Font properties applied to every character in a cell: Bold, Italics, Underline, Font type, Font size, Font color	Text
Paragraph properties applied to every paragraph in the cell	Text

Table 2

5   Majority Cell Style: the unique cell style (composed of table style properties) used most often in a column, row, or table.

Uniform body pattern: a pattern in which the body of a table (the whole table or the whole table minus one or more of the following: heading row, last row, first column, last

10   column) has a single cell style throughout.

Row banding: a pattern in which the rows of a table have alternating shading/border/text styles.

Column banding: a pattern in which the columns of a table have alternating shading/border/text styles.

15   Odd cell for a column, row, or table: a cell that does not match the majority cell style of the row, column, or table.

10

Comparing two cells: reviewing the table styles properties listed above to determine whether two cells have the same cell style.

Determining a Table Style

The methods described in reference to FIGS. 2-11 are used to determine a table style for a table created by a user. The methods begin after the user has created a table and selected to use the table styles inference engine, such as by selecting it from a dropdown menu or selecting it from a toolbar. Of course, there may be other methods for selecting the table styles inference engine. Those skilled in the art will appreciate that the logic flow diagrams of FIGS. 2-11 are executed by the processing unit **21** (FIG. 1) in response to instructions that have been incorporated into the table styles inference engine.

The methods described in reference to FIGS. 2-11 are designed to determine the optimal pattern to describe the user-created table. In order to achieve compatibility with existing table styles, in a preferred embodiment, the present invention determines an optimal uniform body pattern, an optimal row banding pattern and an optimal column banding pattern. The user-defined table is analyzed assuming different uniform body patterns. The optimal uniform body pattern is then determined by determining the uniform body pattern that most closely matches the user-defined table.

The user-defined table is analyzed assuming different row banding body patterns. The optimal row banding body pattern is then determined by determining the row banding body pattern that most closely matches the user-defined table.

The user-defined table is analyzed assuming different column banding body patterns. The optimal column banding body pattern is then determined by determining the column banding body pattern that most closely matches the user-defined table.

From these optimal body patterns, the closest match to the user-defined table is determined to be the overall optimal body pattern. The overall optimal body pattern is then saved as a table style.

Analyzing the User-defined Table Assuming Uniform Body Patterns

Referring now to FIGS. 2-4, methods for analyzing a user-defined table assuming

11

uniform body patterns will be described. The methods described in reference to FIGS. 2-4 are used to analyze the user-defined table assuming it has a uniform body pattern and no type of row or column banding. Different assumptions are made regarding the table (such as that it has no special rows and columns). Based on these assumptions, the user-defined table is analyzed and a score is generated for each assumption. The scores for the different uniform body assumptions are analyzed and the uniform body assumption with the lowest score is determined to be the optimal uniform body assumption.

Referring now to FIG. 2, a method **200** for analyzing a table assuming a uniform body pattern and no special rows or special columns will be described. The method **200** begins at start step **205** and proceeds to step **210** where the majority cell style of the table is determined. The majority cell style represents the cell style (composed of table style properties) most prevalent in the table. In case of a tie between two or more different cell styles, any of the tying cell styles may be selected as the majority cell style. The method then proceeds to step **215**. At step **215**, it is determined the number of odd cells in the table. Odd cells are those that do not match all of the table style properties of the majority cell style. The method then proceeds to step **220** where the number of odd cells is stored as the count for the uniform body pattern and no special rows or special columns assumption. The method ends at step **299**.

Referring now to FIG. 3, a method **300** in accordance with an embodiment of the present invention for analyzing a table assuming a uniform body pattern and assuming special rows and/or special columns will be described. It should be understood that with special rows and/or columns, it is possible that the table has a special first and last row, and a special first and last column. Special means that the row or column is made up of cells with different table style properties than the majority cell style (the rest of the uniform body pattern). Therefore, each combination of special rows and/or columns is analyzed according to the method described in method **300** and a count is determined for each combination. For example, the assumption may comprise:

12

a uniform body pattern with a special first row;

a uniform body pattern with a special last row;

a uniform body pattern with a special first column;

a uniform body pattern with a special last column;

a uniform body pattern with a special first row and special last row;

a uniform body pattern with a special first row and special first column;

a uniform body pattern with a special first row and special last column;

a uniform body pattern with a special last row and special first column;

a uniform body pattern with a special last row and special last column;

a uniform body pattern with a special first column and special last column; etc. (a

uniform body pattern with any combination of the following: special first row, special

last row, special first column and special last column)

The method 300 begins at start step 305 and proceeds to step 310 where an

assumption is made that certain row(s) and/or column(s) are special as described above.

The method then proceeds to step 315. At step 315, the majority cell style for the table

is determined, excluding cells in the rows and columns that were assumed to be special

at step 310. The method then proceeds to step 320.

At step 320, the number (count) of odd cells in the table (those that do not match

the table style properties of the majority cell style) is determined and saved as a count.

Those cells that fall in any rows and columns assumed to be special are not counted. The

method then proceeds to step 325.

At step 325, for each row assumed to be special, the majority cell style for the

row is determined, the number of odd cells in the row (those not matching the majority

cell style for the row) is determined, and the number of odd cells is added to count. The

method then proceeds to step 330.

At step 330, for each column assumed to be special, the majority cell style for the

column is determined, the number of odd cells in the column (those not matching the

majority cell style for the column) is determined, and the number of odd cells is added to

13

count. The method then proceeds to step **335**.

At step **335**, for each corner cell, if both the corner cell's row and column were assumed to be special, then subtract one from count. This is to avoid counting odd corner cells twice. The method then proceeds to step **340** where the value of count is stored for the particular uniform body assumption. The method ends at step **399**.

It should be understood that, in a preferred embodiment, the steps of method **300** are repeated for each combination of special row(s) and/or column(s) with the following constraints:

1.   Check for one special row if $r > 2$

2.   Check for one or two special rows if $r > 3$

3.   Check for one special column if $c > 2$

4.   Check for one or two special column if $c > 3$.

Where r is equal to the number of rows in the user-defined table and c is equal to the number of columns in the user-defined table.

Therefore, a count is determined and saved for each assumed uniform body pattern. These counts are compared to determine the optimal uniform body pattern as will be described below.

Determining the optimal uniform body pattern

Referring now to FIG. 4, a method **400** for determining the optimal uniform body pattern will be described. The method begins at start step **405** and proceeds to step **410** after a count has been determined for all of the uniform body pattern assumptions. At step **410**, it is determined which uniform body assumption has the lowest count. A low count value means the uniform body assumption had the fewest cells that did not fit the assumed pattern. The method then proceeds to decision step **415**.

At decision step **415**, it is determined whether there is a tie for the lowest count between the counts of two or more uniform body assumptions. If not, then the method proceeds to step **420**. At step **420**, the uniform body assumption with the lowest count is the optimal uniform body pattern and the method ends at step **499**. It should be

14

understood that the optimal uniform body assumption will be compared with the optimal row banding assumption and the optimal column banding assumption as described in reference to FIG. 11.

If, at decision step **415**, it is determined that there is a tie for the lowest count between the counts of two or more uniform body assumptions, then the method proceeds to step **425**. At step **425**, tie-breaking procedures are used to determine the optimal uniform body pattern.

In a preferred embodiment, at step **425**, the tied uniform body assumption with the least number of special rows and special columns is selected as the optimal uniform body pattern. If a tie still persists, the tied uniform body assumption with the least number of special last rows and special last columns is selected as the optimal uniform body pattern. If a tie still persists, the tied uniform body assumption with the least number of special columns is selected as the optimal uniform body pattern.

The method then ends at step **499**.

Analyzing Patterns Assuming Row Banding

Referring now to FIGS. 5-7, methods for analyzing a user-defined table assuming row banding patterns will be described. The methods described in reference to FIGS. 5-7 are used to analyze the user-defined table assuming it has a row banding pattern. Different assumptions are made regarding the table (such as that it has no special columns and assuming it has special columns). Based on these assumptions, the user-defined table is analyzed and a score is generated for each assumption. The scores for the different row banding assumptions are then analyzed and the row banding assumption with the lowest score is determined to be the optimal row banding pattern.

Referring now to FIGS. 5-7, a method for analyzing a selected table assuming a row banding body pattern will be described. The method **500** analyzes the table assuming it has a row banding body pattern and no special columns.

The methods of FIGS. 5-7 are used to find the row banding body pattern that most closely matches the body of the table. Banding patterns of *n* different repeating bands

15

with *w* rows per band are used to attempt to match the pattern of the table, where *n* and *w* are defined in a preferred embodiment as:

1. $n = 2$

2. $1 < w < 4$

3. $nw <= r$, where *r* is equal to the number of rows in the user-defined table

Thus, in a preferred embodiment, there can be no more than two bands, the bands can be at most 3 rows wide and an analysis is done only if at least one full pattern fits in the table. For every valid *n* and *w*, each of the methods described in FIGS. 5-6 are attempted.

Referring now to FIG. 5, a method **500** for analyzing a table assuming a row banding body pattern and no special columns will be described. The method **500** allows a table *T'* to be created by removing select rows out of the user-defined table *T* as will be described. The method **500** begins at start step **505** and proceeds to step **507** where a valid *n* and *w* are assumed. The method then proceeds to step **510** when the majority cell style for each row is determined. This style represents the cell style most prevalent in the row. In case of a tie between two styles, the most prevalent style in the table as a whole is selected. If there is still a tie, the style present in the leftmost cell (except the first cell) is selected. The method then proceeds to step **515**.

At step **515**, rows whose majority cell style is not amongst the top *n* row majority styles in the table are removed, with the exception of the first and last rows, which are considered to be special if they are not amongst the top *n*. The method then proceeds to step **520**.

At step **520**, the total number of cells removed at step **515** is saved as count. After the rows are removed at step **515**, the table is composed of bands of the top *n* majority styles. The method then proceeds to step **525**.

At step **525**, all rows in excess of *w* for every band are removed. Removing these rows should make all remaining bands have width less than or equal to *w* as required.

16

The method then proceeds to step **530**.

At step **530**, the total number of cells removed at step **525** is added to the count. The method then proceeds to step **535**.

At step **535**, for every band that has less than w rows, add the number of cells in the first row of the band to count (the last band in the table is excluded from this). The addition of step **535** is performed because having bands that are not of sufficient width takes away from the quality of the banding pattern. The method then proceeds to step **540**.

At step **540**, for each remaining row, determine the number of odd cells that do not match the majority style of the row and add this number to count. These cells also imply a lesser quality of banding and, thus, increase the count. The method then proceeds to step **545** where the value of count is stored for the corresponding row banding assumption. The method ends at step **599**.

It should be understood that the method **500** is repeated for every valid value of n and w and a count is generated for each of the row banding assumptions.

Referring now to FIG. 6, a method **600** in accordance with an embodiment of the present invention for analyzing a table assuming a row banding body pattern and assuming special columns will be described. The method **600** allows a table T' to be created by removing select rows out of the selected table T as will be described.

The method **600** begins at start step **605** and proceeds to step **607** where a valid n and w are assumed. The method then proceeds to step **610** where the majority cell style for each row is determined (excluding any cells shared with any assumed special columns in the calculations). The method then proceeds to step **620**.

At step **620**, rows whose majority style is not amongst the top n row majority styles in the table are removed, with the exception of the first and last rows which are considered to be special if they are not amongst the top n. Removing rows at step **620** leaves bands of the top n majority styles. The method then proceeds to step **625**.

At step **625**, the total number of cells removed at step **620** is saved as the count.

17

The method then proceeds to step **630**.

At step **630**, for each band, all rows in excess of w are removed. Removing the excess rows should make all bands have width less than or equal to w as required. The method then proceeds to step **635**.

At step **635**, the total number of cells removed at step **630** is added to the count. The method then proceeds to step **640**.

At step **640**, for every band (except the last band in the table) that has less than w rows, the number of cells in the first row of the band is added to the count. The addition performed in step **640** is because having bands that are not of sufficient width takes away from the quality of the banding. The method then proceeds to step **645**.

At step **645**, for each remaining row, determine the number of odd cells (excluding the cells in each row that belong to an assumed special column) that do not match the majority style of the row and add this number to the count. The method then proceeds to step **650**.

At step **650**, for each column that we assume to be special, determine the majority cell style for the column, determine the number of odd cells in the column, and add the total to the count. The method then proceeds to step **655** where the value of the count is stored for the assumed row banding assumption. The method ends at step **699**.

It should be understood that, in a preferred embodiment, the steps described in method **600** are repeated for all numbers of special columns with the following constraints:

check for one special column if $c > 2$; and

check for one or two special columns if $c > 3$, where c is equal to the

number of rows in the user-defined table.

Determining the optimal row banding body pattern

Referring now to FIG. 7, a method **700** for determining the optimal row banding pattern will be described. The method **700** determines whether the best row banding results are obtained using the assumption of no special columns, a first special column, a

18

last special column, or two special columns. The count obtained in each of the row banding assumptions (for every valid n and w, assuming 0, 1, or 2 special columns) is examined to determine the lowest count.

The method begins at start step **705** and proceeds to step **710** where, for every row banding assumption analyzed in method **500** and method **600**, it is determined which one has the lowest count at step **710**. The lowest count value indicates that the row banding assumption had the fewest cells that did not fit the assumed pattern. The method then proceeds to decision step **715**.

At decision step **715**, it is determined whether there is a tie for the lowest count between the counts of two or more row banding assumptions. If not, the method proceeds to step **720**. At step **720**, the row banding assumption with the lowest count is the optimal row banding pattern and the method ends at step **799**.

However, if, at decision step **715**, it is determined that there is a tie, then the method proceeds to step **725**. At step **725**, of the tied row banding assumptions the following order of precedence (from preferred to least preferred) is used to determine the optimal row banding pattern: no special columns, a first special column, a last special column, or two special columns. The method **700** then ends at step **799**.

Analyzing Patterns Assuming Column Banding

Referring now to FIGS. 8-10, methods for analyzing a user-defined table assuming column banding patterns will be described. The methods described in reference to FIGS. 8-10 are used to analyze the user-defined table assuming it has a column banding pattern. Different assumptions are made regarding the table (such as that it has no special rows and assuming it has special rows). Based on these assumptions, the user-defined table is analyzed and a score is generated for each assumption. The scores for the different column banding assumptions are then analyzed and the column banding assumption with the lowest score is determined to be the optimal column banding pattern.

Referring now to FIGS. 8-10, a method for analyzing a selected table assuming a column banding pattern will be described. The method **800** analyzes the table assuming

19

it has a column banding pattern and no special rows.

The methods of FIGS. 8-10 are used to find the column banding pattern that most closely matches the body of the user-defined table. Banding patterns of n different repeating bands with w columns per band are used to attempt to match the pattern of the table, where n and w are defined in a preferred embodiment as:

$n = 2$;

$1 < w < 4$; and

$nw <= c$, where c is equal to the number of columns in the user-defined

table

Thus, in a preferred embodiment, there can be no more than two bands, the bands can be at most 3 columns wide and an analysis is done only if at least one full pattern fits in the table. For every valid n and w, each of the methods described in FIGS. 8-9 is attempted.

Referring now to FIG. 8, a method **800** in accordance with an embodiment of the present invention for analyzing a table assuming a column banding pattern and no special rows will be described. The method **800** allows a table T' to be created by removing select columns out of the selected table T as will be described. The method **800** begins at start step **805** and proceeds to step **807** where a valid n and w are assumed. The method then proceeds to step **810** where the majority cell style for each column is determined. This style represents the cell style most prevalent in the column. In case of a tie between two styles, the most prevalent style in the table as a whole is selected. If there is still a tie, the style present in the uppermost cell (except the first cell) is selected. The method then proceeds to step **815**.

At step **815**, columns whose majority cell style is not amongst the top n column majority styles in the table are removed, with the exception of the first and last columns, which are considered to be special if they are not amongst the top n. Removing the columns at step **815** leaves the bands of the top n majority styles. The method then proceeds to step **820**.

20

At step **820**, the total number of cells removed at step **815** is saved as the count. The method then proceeds to step **825**.

At step **825**, all columns in excess of w for every band are removed. The method then proceeds to step **830**.

At step **830**, the total number of cells removed at step **825** is added to the count. This should make all bands have width less than or equal to w as required. The method then proceeds to step **835**.

At step **835**, for every band that has less than w columns, the number of cells in the first column of the band is added to the count (the last band in the table is excluded from this). The addition of step **835** is performed because having bands that are not of sufficient width takes away from the quality of the banding. The method then proceeds to step **840**.

At step **840**, for all remaining columns, the number of odd cells that do not match the majority style of the column is determined and added to the count. These cells imply a lesser quality of banding and, thus, increase the value of the count. The method then proceeds to step **845** where the count is stored. The method ends at step **899**.

It should be understood that the method **800** is repeated for every valid value of n and w and a count is generated for each of the column banding assumptions.

Referring now to FIG. 9, a method **900** in accordance with an embodiment of the present invention for analyzing a table assuming a column banding body pattern and assuming special rows will be described. The method **900** allows a table T' to be created by removing select columns out of the selected table T as will be described.

The method **900** begins at start step **905** and proceeds to step **907** where a valid n and w are assumed. The method then proceeds to step **910** where the majority cell style for each column is determined (excluding any cells shared with any assumed special rows in the calculations). The method then proceeds to step **920**.

At step **920**, columns whose majority style is not amongst the top n column majority styles in the table are removed, with the exception of the first and last columns

21

which are considered to be special if they are not amongst the top n. Removing the cells at step **920** leaves bands of the top n majority styles. The method then proceeds to step **925**.

At step **925**, the total number of cells removed at step **920** is saved as the count. The method then proceeds to step **930**.

At step **930**, for every band, all columns in excess of w are removed. This should make all bands have width less than or equal to w as required. The method then proceeds to step **935**.

At step **935**, the total number of cells removed at step **930** is added to the count. The method then proceeds to step **940**.

At step **940**, for every band (except the last band in the table) that has less than w columns, the number of cells in the first column of the band is added to the count. The addition performed in step **940** is because having bands that are not of sufficient width takes away from the quality of the banding. The method then proceeds to step **945**.

At step **945**, for all remaining columns, the number of odd cells (excluding the cells in each column that belong to an assumed special row) that do not match the majority style of the column is determined and added to the count. The method then proceeds to step **950**.

At step **950**, for each row assumed to be special, the majority cell style for the row is determined, the number of odd cells in the row is determined, and the total is added to the count. The method then proceeds to step **955** where the count is stored. The method ends at step **999**.

It should be understood that, in a preferred embodiment, the steps described in method **900** are repeated for all numbers of special rows with the following constraints:

check for one special row if $r > 2$; and

check for one or two special rows if $r > 3$, where r is equal to the number of rows in the user-defined table.

Determining the optimal row banding body pattern

Referring now to FIG. 10, a method **1000** for determining the optimal column banding pattern will be described. The method **1000** determines whether the best column banding results are obtained when we assume no special rows, a first special row, a last special row, or two special rows. The count obtained in each of the cases (for every valid n and w, assuming 0, 1, or 2 special rows) is examined to determine the lowest count.

The method begins at start step **1005** and proceeds to step **1010** where, for every column banding assumption analyzed in method **800** and method **900**, it is determined which one has the lowest count. The lowest count value indicates that the column banding assumption had the fewest cells that did not fit the assumed pattern. The method then proceeds to decision step **1015**.

At decision step **1015**, it is determined whether there was a tie between two or more column banding patterns for the lowest count. If not, the method proceeds to step **1020**. At step **1020**, the column banding body assumption with the lowest count is the optimal column banding body pattern and the method ends at step **1099**.

However, if, at decision step **1015**, it is determined that there is a tie between two or more column banding patterns, then the method proceeds to step **1025**. At step **1025**, of the tied column banding patterns, the following order of precedence (from preferred to least preferred) is used to determine the optimal column banding pattern: no special rows, a first special row, a last special row, or two special rows. The method **1000** then ends at step **1099**.

Determining Overall Optimal Pattern

After determining an optimal uniform body pattern, an optimal row banding pattern and an optimal column banding pattern, a method **1100** for determining the optimal table pattern is performed. The method **1100** begins at start step **1105** and proceeds to step **1110** where the values of the count determined for the optimal column banding pattern, optimal row banding pattern, and optimal uniform body pattern are

23

compared and the pattern with the lowest count is determined. The pattern with the lowest count is the optimal pattern. If there is a tie between two or more patterns, the optimal pattern is selected in the following order of precedence: optimal uniform body pattern, optimal row banding pattern, and optimal column banding pattern. The method then proceeds to step **1115**.

At step **1115**, it is determined whether the optimal pattern determined at step **1110** has special corner cells. A corner cell is special if:

its row and column are special; and

its cell style does not match the majority cell style of its row; and

its cell style does not match the majority cell style of its column.

After step **1115**, the best possible pattern for the table has been determined and the method ends at step **1199**.

It should be understood that after a best possible pattern has been determined, then that is by definition the table style for the table. A style comprises:

cell style for cells of the whole table;

cell style for any row bands;

cell style for any column bands;

cell style for cells of any special rows;

cell style for cells of any special columns; and

cell style for special cells.

The best possible pattern determines all of these cell styles so the best possible pattern is stored as the table style.

It should be understood that the foregoing pertains only to the preferred embodiments of the present invention, and that numerous changes may be made to the embodiments described herein without departing from the spirit and scope of the invention.
